**RELATED APPLICATIONS**

This application is a continuation-in-part of U.S. Patent Application Serial No.  
10/183,580, filed June 26, 2002, which was a continuation-in-part of U.S. Patent Application  
5 Serial No. 09/781,818, filed February 12, 2001, now U.S. Patent No. 6,462,249.

### **FIELD OF THE INVENTION**

This invention relates generally to processes for decontaminating contaminated materials, such as chemical weapon components, and, more specifically, to processes for decontaminating contaminated materials without using incineration methods.

5

### **BACKGROUND OF THE INVENTION**

The decontaminating of contaminated material can be very difficult. This is especially the case with respect to the decommissioning of chemical weapons carrying chemical warfare agents. The principal problem in this regard is how to safely remove, neutralize and dispose of the extremely toxic chemical warfare agents used in such chemical weapons. Modern technology has become increasingly successful in the neutralization of these chemical warfare agents -- once the agents have been removed from the chemical weapon housing. However, after the bulk of the chemical warfare agents have been removed from the chemical weapons housings, the housings and their various components typically remain contaminated with residual amounts of the chemical warfare agents. The decontamination of these chemical weapon components remains a difficult problem.

Most prior art methods for decontaminating chemical weapon components have employed a two-step process. In a first step, the components are subjected to liquid chemicals or to high temperatures to remove and decompose essentially all of the chemical warfare agents adhering to the chemical weapon components. In a second step, residual vapors from the first step are incinerated to eliminate any and all residual chemical warfare agents in those vapors.

The incineration step has now been questioned, however, as possibly allowing potentially toxic combustion products to be released to the atmosphere. Accordingly, the incineration step has been banned in many industrial countries, including in the United States.

Thus, there is a need for a new method of decontaminating chemical weapon components which completely eliminates all traces of chemical warfare agents in an efficient and inexpensive manner, and without the use of an incineration step.

### **SUMMARY**

The invention satisfies this need. The invention is a process for the low temperature, non-incineration decontamination of contaminated materials containing hazardous agents, the process comprising (a) contacting the contaminated materials and the hazardous agents with steam at substantially ambient pressure in a substantially dry first heated vessel for a period of at least about 15 minutes, the steam being at a temperature of at least about 560°C, whereby essentially all of the hazardous agents are removed from the contaminated materials, (b) removing a first gaseous discharge stream containing hazardous agents from the first heated vessel, the first gaseous discharge stream comprising a condensible moiety and a non-condensable moiety, (c) heating the first gaseous discharge stream at substantially ambient pressure in a substantially dry second vessel to at least about 500°C and maintaining the first gaseous discharge stream in the second vessel of at least about 500°C for a period of at least about one second in an atmosphere containing sufficient steam such that at least about 99 weight percent of the hazardous agents within the first gaseous discharge stream are converted to non-hazardous agents, (d) removing a second gaseous discharge stream containing a reduced concentration of hazardous agents from the second vessel, the second gaseous discharge stream comprising a condensible moiety and a non-condensable moiety, and (e) catalytically treating the second gaseous discharge stream in the presence of oxygen so that the concentration of hazardous agents within the non-condensable moiety of the second gaseous discharge stream is reduced to less than about 1.0 mg/m<sup>3</sup> at standard temperature and pressure.

The process is especially applicable where the contaminated materials are chemical weapon components and the hazardous agents are chemical warfare agents.

### **DRAWINGS**

These features, aspects and advantages of the present invention will become better understood with regard to the following description, appended claims and accompanying figures where:

### **DETAILED DESCRIPTION**

The following discussion describes in detail one embodiment of the invention and several variations of that embodiment. This discussion should not be construed, however, as limiting the invention to those particular embodiments. Practitioners skilled in the art will recognize numerous other embodiments as well.

The invention is a process for the low temperature, non-incineration decontamination of contaminated materials containing hazardous agents. By "hazardous agents," it is meant any chemical compound or material which is considered harmful to humans and/or other life forms. Hazardous agents are typically organic in nature, but can also be toxic metals or metal compounds which are volatilized at temperatures between 560°C and 750°C. Such metals include mercury and lead.

The invention is especially applicable to the decontamination of chemical weapon components, wherein the hazardous agents are chemical warfare agents. By the term

“chemical warfare agents,” it is meant any chemical which, through its chemical action on life processes, can cause death, temporary incapacitation or permanent harm to humans or animals.

In the process, as illustrated in Figure 1, the chemical weapon components **10**, such as missile warheads or bombs, are opened and the chemical warfare agents contained therein are flushed out. That portion of the chemical warfare agents flushed out of the chemical weapon components **10** are then removed to a separate treating facility (not shown) for pacification.

After being flushed out, the chemical weapon components **10** continue to be contaminated with residual amounts of the chemical warfare agents. These flushed out, but still contaminated, chemical weapon components **10** are next sealed within a substantially dry first heated vessel **12**. Within the first heated vessel **12**, the chemical warfare agents are contacted with steam at a substantially ambient pressure for a period of at least about 15 minutes, typically for a period of between about 15 minutes and about 4 hours, most typically for a period between about 15 minutes and about 2 hours. By “substantially ambient pressure,” it is meant at a pressure between about 14.5 psia and about 14.7 psia.

The temperature of the steam in contact with the chemical warfare agents within the first heated vessel **12** is at least about 560°C, and is typically between about 560°C and about 750°C. By this contacting step, essentially all of the chemical warfare agents within, and adhering to, the chemical weapon components **10** are removed from the chemical weapon components **10** and transferred into a gaseous steam-containing phase.

The gaseous, steam-containing phase containing the chemical warfare agents in the first heated vessel **12** is removed from the first heated vessel **12** via a first discharge line **16** as a first gaseous discharge stream. This first gaseous discharge stream comprises a condensible moiety and a non-condensable moiety.

After removal from the first heated vessel **12**, the first gaseous discharge stream is heated in a substantially dry second vessel **18** at substantially ambient pressure to at least about 500°C. (typically between about 500°C and about 700°C). Within the second vessel **18**, the first gaseous discharge stream is maintained at a temperature of at least about 500°C for a

period of at least about one second in an atmosphere containing steam. Typically, the steam and the second vessel **18** is at a concentration between about 150% and about 350% of stoichiometry, preferably between about 250% and about 300% of stoichiometry, and most preferably between about 225% and about 275% of stoichiometry. Typically, the first gaseous discharge stream is thus maintained within the second vessel for a period of between about 1 and 10 seconds, most typically between about 1 and about 5 seconds. The term “stoichiometry” in this sense is meant to indicate the quantity of steam theoretically capable of reacting all of the chemical warfare agents within the first gaseous discharge stream to non-chemical warfare agents. By this step, at least about 99 wt. %, typically at least about 99.9 wt. % and, most typically, at least about 99.99 wt. %, of the chemical warfare agents within the first gaseous discharge stream are converted to non-chemical warfare agents.

The gaseous mixture within the second vessel **18** is removed from the second vessel **18** via the second gaseous discharge line **20** to a reactor **28** as a second gaseous discharge stream. This second gaseous discharge stream also comprises a condensible moiety and a non-condensible moiety.

The non-condensable moiety of the second discharge gaseous stream is removed from the second vessel **18** where it is catalytically treated in the presence of oxygen so as to reduce the concentration of chemical warfare agents within the non-condensable moiety to less than about 1.0 mg/m<sup>3</sup> (at standard pressure and temperature). This catalytic treatment step can be carried out in one of a large number of catalytic oxidation processes known in the art, such as the Thermatrix Blameless Oxidation process licensed by Thermatrix, Inc. of California, Edge II™ licensed by Alzeta Corporation of California and Econ-Abator Catalytic Oxidation Systems licensed by Huntington Environmental Systems of Illinois. The CATOX Process licensed by Honeywell, Inc. of Morristown, New Jersey has been found to be particularly effective in the oxidation of chemical warfare agents within the non-condensable moiety of the second discharge stream to non-chemical warfare agents. This process is disclosed in detail in U.S. Patent No. 6,080,906, the entirety of which is incorporated herein by this reference.

As illustrated in Figure 2, the chemical weapon components **10** can be flushed out using a flushing apparatus **30** comprising a primary flushing vessel **32** and a secondary flushing vessel **34**. In the primary flushing vessel **32**, the chemical weapon components **10** are initially opened and the mobile chemical warfare agents contained therein are dumped into the bottom of the primary flushing vessel **32** for removal to the separate treating facility **36**. After  
5 substantially all of the mobile chemical warfare agents have gravitated out of each chemical weapon component **10**, the chemical weapon component **10** is placed into the secondary flushing vessel **34**.

The secondary flushing vessel **34** contains a rotating carousel **38** which is partially  
10 submerged within a quantity of liquid flushing agent **40**, such as water or other solvent. The carousel **38** rotates individual chemical weapon components **10** into and out of the flushing agent. Both above and below the liquid level **42**, high pressure sprayers **44** are capable of spraying liquid flushing agent into the open ends **46** of the chemical weapon components **10** to flush out additional amounts of chemical warfare agents.

Preferably, the carousel **38** is adapted to retain each chemical weapon component **10** at  
15 an angle of between about 30° and about 90° with respect to the horizontal so that the open end **46** of each chemical warfare component **10** is canted downwardly when the chemical weapon component **10** is disposed at the top of the carousel **38** and is canted upwardly when rotated to the bottom of the carousel **38**. By this design, the chemical weapon components **10**  
20 within the carousel **38** automatically drain when rotated to the top of the carousel **38** and automatically draw liquid into each chemical weapon component **10** when rotated to the bottom of the carousel **38**.

After exiting the secondary flushing vessel **34**, the chemical weapon components **10** are placed into the first heated vessel **12** where they are contacted with steam as described above.  
25 As illustrated in the drawings, the first heated vessel **12** can be equipped with electrical heating coils **47** so that the first heated vessel **12** can be heated electrically, preferably by induction heating.

Operation of the first heated vessel **12** can be carried out in a batch-wise mode or can be carried out in a semi-batch, semi-automatic or fully automatic modes. Figure 3 illustrates the operation of the first heated vessel **12** in a semi-batch mode. As illustrated in Figure 3, the first heated vessel **12** houses a pair of discrete bundles **48** of chemical weapon components **10**. Typically, each bundle **48** is a palletized plurality of chemical weapon components **10**. Each bundle **48** is subjected to two separate applications of heated steam. After each application, the forward-most bundle **48a** is removed from the outlet end **50** of the first heated vessel **12**, the rearward-most bundle **48b** is moved forward within the first heated vessel **12** and a new bundle **48c** is disposed within the first heated vessel **12** at the inlet end **52** of the first heated vessel **12**.

In another embodiment (not shown), chemical weapon components **10** are loaded onto one or more trays which are pushed through the first heated vessel **12** in a similar fashion as the bundles **48** described immediately above.

Figures 4A and 4B illustrate a semi-automatic embodiment. In this embodiment, a plurality of elongate racks **54** are disposed within the first heated vessel **12**. Each rack **54** is adapted to accept, end-to-end, a plurality of individual chemical weapon components **10**. A charging mechanism (not shown) is disposed at the inlet end **52** of the first heated vessel to charge one chemical weapon component **10** at a time into the inlet end **56** of one of the racks **54**. As one chemical weapon component **10** is charged into the inlet end **56** of a rack **54**, a fully decontaminated chemical weapon component **10** is removed at the outlet end **58** of that rack **54** by a discharging mechanism (not shown). Either the charging and discharging mechanisms or the racks **54** rotate about the longitudinal axis **59** of the first heated vessel **12** so that the charging mechanism loads a chemical weapon component **10** into each of the racks **54** in repeated, serial fashion. By this operation, all of the racks **54** are serially loaded and unloaded.

Figure 5 illustrates yet another embodiment of the invention. This embodiment of the invention can be operated in either a semi-automatic or full automatic configuration. In this embodiment, an auger **60** is disposed within the first heated vessel **12**. Its configuration is

suitable for chemical weapon components **10** of relatively reduced size, such as pre-shredded chemical weapon components **10**. In this embodiment, as the auger **60** slowly rotates, chemical weapon components **10** are slowly moved from the inlet end **52** of the first heated vessel **12** towards the outlet end **50** of the first heated vessel **12**.

5 In many cases, operation of this embodiment is facilitated by loading the chemical weapon components **10** within the first heated vessel **12** with a filler material, such as crushed limestone, aluminum silicate or granulated charcoal. Typically, the filler material is comprised of clumps having a width between about 1/4 inch and about 1 inch, typically between about 1/4 inch and about 1/2 inch. In a typical operation, such filler material comprises between about  
10 one third and about two thirds of the volume of loose material within the first heated vessel **12**. The filler material is removed at the outlet end **50** of the first heated vessel **12** with the fully decontaminated chemical weapon components. The filler material is then separated from the chemical weapon components **10**, such as by screening or air blasting. Thereafter, the filler material can be recycled for repeated uses within the process.

15 Figure 6 illustrates in detail an auger configuration useful in this embodiment. In this configuration, the auger **60** is composed of an axially rotating central member **62** to which is attached a plurality of outwardly radiating support members **64**. The support members **64** are disposed in a spiral about the central member **62**. At the distal end of each support member **62** is an auger blade **66**. In the embodiment illustrated in Figure 6, each auger blade **66** is L-  
20 shaped, having a lateral component **68** and a vertical component **70**. The auger blades **66** are attached to the support elements **64** in an adjustable fashion, such as by being attached with a bolt and nut **72**. By being adjustable, the angle of the individual auger blades **66** can be optimally adjusted to smoothly move loose material through the first heated vessel **12**.

25 For many materials, it has been found that varying the angle of the auger blades **66** along the length of the auger **60** can be beneficial. In some operations, it can actually be beneficial to angle some of the auger blades **66** to nudge material backwards within the first heated vessel **12** while the remainder of the auger blades **66** are angled to push the material

forward. Such a configuration has been found to be advantageous in maintaining the smooth flow of certain materials through the first heated vessel 12.

The invention has been found to provide an extremely effective method for decontaminating chemical weapon components without having to resort to incineration steps.

5 Because the process is carried out at substantially ambient pressures, capital, operating and maintenance costs are reduced to a minimum. The invention can also provide an effective method for minimizing the overall quantity of a "mixed" waste containing organic contaminants and radioactive contaminants. The non-radioactive portion of any such mixed waste can be substantially eliminated by use of the invention, thus minimizing the overall  
10 quantity of waste which must be disposed of. The invention has also been further found to provide an effective method for decontaminating other contaminated materials containing hazardous agents, such as contaminated soils.

Having thus described the invention, it should be apparent that numerous structural modifications and adaptations may be resorted to without departing from the scope and fair  
15 meaning of the instant invention as set forth hereinabove and as described hereinbelow by the claims.
